Abstract

It is well established that recent immigrants earn considerably less than their native-born counterparts even after adjusting for differences in human capital. Another labour market trend has been the growth in non-standard forms of employment. Since non-standard forms of work are generally less desirable than standard jobs on a number of dimensions including earnings, this study examines the nexus between immigrant earnings and non-standard employment to investigate if there is a systemic connection between the two trends. Consistent with earlier research evidence, we find a substantial earnings disadvantage associated with all forms of non-standard work relative to full-time, permanent employment. Conditioning on observable characteristics, immigrants are less likely to be employed in full-time, permanent work. However, when we examine workers in non-standard jobs, we find that immigrant–non-immigrant earnings gaps are *smaller* than those observed among workers in standard jobs. Moreover, the unadjusted mean earnings of long-term immigrants in part-time jobs are actually *higher* than the earnings of similarly employed Canadian-born workers. Finally, considering immigrants from Western and non-Western countries, we find that the earnings disadvantage of non-Western immigrants in non-standard jobs is *smaller* than the earnings disadvantage of non-Western immigrants in standard jobs. These findings

suggest that non-standard jobs provide a point of entry for many new immigrants into the Canadian labour market. But whether these jobs are a bridge to upward mobility or whether they act as traps from which immigrants are unable to escape is a question that needs to be answered with better longitudinal data that track specific cohorts of workers.

INTRODUCTION

Current concerns over growing economic inequality are well supported by evidence. The fact that labour markets are becoming increasingly insecure for many workers even as incomes have grown for managers and professionals has been widely documented. By some accounts, non-standard forms of employment such as part-time and temporary (i.e. fixed term) work can be as high as one-third of all jobs (Busby & Muthukumaran, 2016, 4). In recent decades, new immigrants have arrived to find that a large number of employment opportunities accessible to them are non-standard forms of employment. However, empirical research on how the growth in non-standard employment has affected immigrants' integration into the labour market has not received equal attention.

Broadly stated, this study proposes to examine the role that non-standard employment may play in facilitating (or hindering) integration of immigrants into the Canadian labour market. It is generally accepted that non-standard employment is less desirable than standard employment even though some workers may accept non-standard work in order to accommodate other personal priorities such as caregiving, education and training, or simply enjoy the flexibility that non-standard employment may provide. Since non-standard work is often viewed as less desirable, it is possible that immigrants would be overrepresented in this type of employment. Native-born workers may be reluctant to take non-standard jobs given the lower pay, fewer benefits and greater uncertainty in hours of work, to name only a few characteristics of such employment. What is less obvious about immigrants taking non-standard jobs is whether immigrant earnings in non-standard employment would have the same discount that previous studies have found in the overall labour market. At first glance, if one extrapolates earning patterns from standard employment, we may expect immigrants to earn less, all else being equal, in non-standard employment as well. While there is some evidence from a previous study on 'precarious' jobs, less is known about the different types of non-standard employment (Hira-Friesen, 2018b). It is possible that within the labour market the supply of immigrant labour and employers' demand for flexible workers creates the conditions for a unique matching. Employers want flexibility and lower cost (Houseman, 2003), while immigrants want jobs that will not only bring much needed income, but also a chance to add Canadian qualifications to their resume. This type of matching could be a win-win for both sides and employers may just be willing to pay the same earnings for similar work. Additionally, this type of matching would be especially suited to new immigrants' needs because they are under pressure to accept any employment that can begin to bring in even a subsistence income. If the labour market were tight (i.e. an expanding economy and low unemployment), employers may even be forced to compete for scarce immigrant workers, thus raising the earnings necessary to attract the best workers. If non-standard employment, then, serves as a conduit for immigrants, particularly recent immigrants (e.g. Fuller, 2011; Fuller and Stecy-Hildebrandt 2014), then there is relatively less worry over the existence and distribution of non-standard employment. If, on the other hand, non-standard employment creates a secondary labour market wherein participants are 'trapped' in undesirable employment, the prevalence of non-standard work and the potential overrepresentation of immigrants in these forms of employment, is cause for greater concern. Accordingly, this

study proposes to fill an important gap in our knowledge of the role of non-standard employment in the immigrant labour market experience.

We seek to answer three specific research questions: Firstly, what are the earnings gaps between standard and several categories of non-standard jobs? Secondly, are immigrants over (under) represented in our categorizations of non-standard work? Thirdly, are immigrant-non-immigrant wage disparities larger or smaller in standard versus non-standard jobs? Using data from the Canadian Labour Force Survey (LFS), we compute OLS estimates of hourly earnings differentials first among Canadian-born workers in standard and non-standard employment categories. We then use multinomial logistic regressions to estimate whether immigrants are more (less) likely to be employed in standard or non-standard work conditioned on a set of observable characteristics. Next, we use interaction terms to investigate whether the earnings effect of non-standard work is different for immigrants relative to native-born workers. Finally, we estimate and decompose immigrant-non-immigrant earnings disparities among similarly employed workers across several categories of non-standard relative to standard employment.

CONCEPTUAL FRAMEWORK

Non-standard employment in Canada

The share of non-standard jobs in Canada grew dramatically in the early 1980s and 1990s following the two recessionary periods in each decade, but has become relatively stable since the mid-2000s (e.g. Vosko et al, 2003; Busby & Muthukumaran, 2016). According to one recent report, non-standard work accounts for just over one-third of all employment, with part-time work representing about half of all non-standard employment in Canada (Busby & Muthukumaran, 2016, 4). Increases in non-standard employment over the past roughly two decades have been driven, among other factors, by a surge in the number of full-time, temporary jobs, which grew 56 per cent from 1997 to 2015 (Busby & Muthukumaran, 2016, 4). Employers are generally attracted to creating non-standard jobs for two reasons: matching fluctuations in demand for their products and services with a flexible supply of labour and lowering the cost of production by hiring lower cost labour (Houseman, 2003).

Following previous research examining non-standard work (Gomez and Lamb, 2019; Lamb and Chatoor 2019), we consider a standard job as one that is full-time and permanent and, as such, often more desirable. Non-standard work, then, can include jobs that are part-time, contract, casual, seasonal or any other form of non-permanent work. Non-standard work can be viewed as forming the second (and lower) layer of employment in a segmented labour market. In segmented labour markets, non-standard work typically belongs to the secondary sector owing to the often-poor quality, inherent instability and relatively low earnings of many non-standard jobs (e.g. Leontaridi, 1998; Dickens & Lang, 1984; Reich, Gordon & Edwards, 1973). Therefore, non-standard work has real potential to exacerbate inequalities by the fact that 'the advantages of non-standard work are frequently offset by less job security, lower pay and fewer fringe benefits' (Krahn, 1995, 35). Noack and Vosko (2011, 3) define precarious jobs as those that are 'characterized typically by high levels of uncertainty, low income, a lack of control over the labour process, and limited access to regulatory protections'. While there is obvious overlap between the concepts of non-standard work and employment precarity, it is important to emphasize that non-standard work need not *necessarily* be precarious employment (ILO, 2016, 18).

Extant research emphasizes the relationship between non-standard employment and a number of negative outcomes (Kalleberg, Reskin and Hudson 2000; McGovern et al. 2004), such as: job insecurity (De Witte and Näswall, 2003; Vosko, 2000), lower earnings and fewer workplace benefits (Arranz et al., 2018; Tabi and Langlois 2003). Workers in non-standard jobs are therefore often less likely to be able to save money or buy a home (McGrath and Keister, 2008). They are also at greater risk for workplace injuries relative to those with full-time, permanent employment (Underhill and Quinlan 2011). Lastly, non-standard forms of employment increase

workers' stress and result in adverse mental and physical health outcomes (Jamal, 2004), and lower job satisfaction (Bergman, 2002; Buddelmeyer et al. 2015).

The potentially harmful consequences notwithstanding, non-standard employment may offer personal flexibility thereby allowing workers to balance caregiving commitments, engage in human capital accumulation (by returning to education or training) or smooth transitions from school to work or into retirement (e.g. Vosko et al, 2003). For immigrants in particular, Fuller (2011, 160) suggests that employers may use temporary positions as a way of 'testing' out potential employees for permanent employment who would otherwise be deemed 'too risky to hire' (Fuller, 2011, 160). Thus, a non-standard job can be viewed as a point of entry into the labour market for workers with low human capital or, as in the case of recent immigrants, high levels of education but little or no experience in the host country labour market. Non-standard jobs, in this view, despite being inferior to standard jobs, create opportunities for less employable workers to gain work experience and thereby accumulate human capital.

The growth of non-standard employment has been found to disproportionately affect socially disadvantaged groups such as women, immigrants, racialized minorities, etc. (Lewchuck and Lafleche, 2014). Newly arrived immigrants, in particular, are significantly more likely than Canadian-born workers to be working in non-standard jobs (Lewchuk et al. 2013; Noack and Vosko 2011, 1), less likely to be covered by a collective agreement (Gomez and Lamb 2016), and less likely to access high-quality employment in their respective field (e.g. Sweetman et al, 2015). Hira-Friesen (2018a, 45) finds that immigrants (both recent and established) are overrepresented in involuntary part-time work relative to Canadian-born workers, while recent immigrants are also overrepresented among temporary jobholders as compared to Canadian-born and established immigrants.

Immigrant disadvantage in earnings and employment

The literature on immigrant employment and earnings upon entering the labour market has two fairly robust findings: immigrants face a significant disadvantage in both employment and earnings compared to the native-born workers with similar human capital (Tossutti, 2013). Numerous studies document that immigrant earnings are discounted relative to the earnings of their Canadian-born counterparts (e.g. Aydemir and Skuterud 2005; Baker & Benjamin, 1994; Banerjee, 2009; Bloom et al. 1995; Frenette & Morissette, 2005; Grant, 1999; Green and Worswick 2012; Hou, 2013; Zhang & Banerjee, 2019; Li, 2003; Reitz, 2001). At the occupational level, Smith and Fernandez (2017, 67) find a similar pattern in all fields with the exception of professional occupations. Moreover, evidence shows that the earnings gap for recent immigrants continued to widen. Aydemir and Skuterud (2005) found evidence of further declines in the earnings of successive cohorts of recent immigrants in the 1980s and 1990s.

To our knowledge, Hira-Friesen (2018b) is the only Canadian study to consider the relationship between immigrant and non-immigrant earnings in various forms of employment. This study examines the wage impact of several categories of precarious work: involuntary part-time work, multiple job holding and temporary employment. Unsurprisingly, all categories of precarious work are statistically significant and negatively related to earnings. Among females, immigrants with multiple jobs appear to earn *more* than immigrant single jobholders (the coefficients on the interaction terms between multiple jobholding and immigrant status are positive and statistically significant). However, these effects are not large enough to compensate for the overall negative returns to immigrant status and multiple jobholding. Among males, precarious employment does not have a differential effect on earnings, except for long-term immigrants in temporary jobs. For this group, precarious employment has a particularly negative effect on earnings (Hira-Friesen, 2018b).

In this study, we are able to further build upon the work of Hira-Friesen (2018b) in a number of ways to better understand the connection between immigrant status and non-standard employment. We use a different classification of employment with four mutually exclusive categories: full-time-permanent (i.e. the standard job), and three sub-groups of non-standard jobs: full-time-non-permanent, part-time-voluntary and

part-time-involuntary. Our classification differs from Hira-Friesen's in two ways: first, we exclude self-employment because it is qualitatively different from other forms of employment; second, our groups better capture non-standard employment while Hira-Friesen's categories are better for describing precarious employment.

In our analyses, we also consider two sources of heterogeneity within the immigrant group. First, the distinction between recent versus longer-term immigrants is modelled because there is strong evidence to suggest that immigrant earnings rise over time despite the significant earnings gap upon arrival in Canada. Second, it is also known that immigrants of 'colour', termed visible minorities in Canada, have been increasing in number in recent years and that they experience an earnings gap relative to immigrants considered 'white', who usually have a European heritage.

First, we compute the wage differential between standard and non-standard jobs among Canadian-born workers so as to avoid, for the moment, the confounding effects of immigrant status. We then examine the extent to which immigrants are over (under) represented in the proposed classifications of standard/non-standard work. Finally, we estimate and decompose earnings differentials between immigrants and non-immigrants employed in the same form of standard or non-standard work. Our treatment of immigrants of non-European heritage is slightly different because the LFS does not ask any question regarding the race of the respondent. Instead, the question asks, from which country the respondent immigrated? We use this question to create a proxy for immigrants of 'colour'. This is explained in detail in the next section.

The overarching objective of this study is to better understand the extent to which non-standard work may contribute to the relative economic position of recent immigrants in Canada. A segmented labour market theory would predict that immigrants lacking Canadian credentials would be pushed into accepting the less desirable non-standard jobs that native-born Canadians avoid. Certainly, this pattern has been shown to exist by other studies (e.g. Aydemir and Skuterud 2008). What is less obvious, however, is whether and to what extent, immigrant earnings in non-standard jobs are discounted as compared to the immigrant earnings disadvantage observed in standard employment. It is entirely possible that given their high level of education (and skills) immigrants earn *more* money in non-standard work than their similarly employed native-born counterparts. This is the empirical question that we attempt to answer in this paper.

DATA AND METHODS

Data for the present analysis are taken from the master files of the Canadian Labour Force Survey (LFS) for the years 2006 to 2016 inclusive. The LFS is a national, cross-sectional survey representative of private households in Canada's ten provinces. The LFS is a monthly survey conducted by Statistics Canada whereby interviewers obtain individual level information from each sampled household by proxy (i.e. from one household member). Interviews are conducted in-person, by phone or electronically and response to the LFS is mandatory (Statistics Canada, 2014).¹ The rotating panel sampling design of the LFS means that the same households (and thus individual respondents) could be included in the data for up to six months; therefore, to ensure that our sample does not include repeated measures of the same respondents, we use only data from January for each year. To improve sample size, especially for recent immigrant cohorts, we stack data from 2006 through to 2016.

Questions related to immigration were first introduced in the LFS in 2006 (Statistics Canada, 2014) making this the earliest possible point of comparison for immigrant-non-immigrant labour market outcomes. Our outcome of interest is the natural logarithm of hourly earnings converted to 2016 constant dollars.² The measure of nominal hourly earnings available in the LFS is calculated using usual paid hours per week (Statistics Canada, 2014, 18). As our focus is on earnings, we restrict the sample to persons aged 15 to 65 years who are employed with positive, non-missing hourly earnings; self-employed persons and respondents who are unemployed or not in the labour force are therefore excluded from the sample. We are interested in the earnings of immigrants relative to their non-immigrant counterparts; we define an immigrant to be anyone born outside of Canada who responded 'yes' to

being a landed immigrant. Persons who report being born outside of Canada, but who are not landed immigrants, are also excluded from the analysis. We further define two cohorts of immigrants created by subtracting the year of immigration from the survey year: recent immigrants, those who arrived in Canada within 10 years of the survey data collection; and long-term immigrants, those who arrived in Canada 11 or more years from the date of LFS sampling. Since our sample is further stratified by gender and employment type, sample size restrictions preclude more detailed classifications of immigrant groups.

Non-standard work can be conceptualized in a number of ways. Based on the variables available in the LFS, we define standard work as any employment that is both fulltime and permanent. Non-standard, then, is work that is not full-time, permanent (i.e. part-time and/or non-permanent work). Therefore, we employ four categories of work: full-time, permanent (i.e. 30 hours a week or more); full-time, non-permanent; voluntary part-time (i.e. 30 hours a week or less) and involuntary part-time. An important feature of the LFS is that it allows for the differentiation between voluntary and involuntary part-time work. We define involuntary part-time to refer to any respondent currently working part-time, but who *wants* full-time work (regardless of whether or not full-time work is available/feasible for a particular respondent). The relatively small number of part-time workers in the data, particularly among males, makes further delineation of part-time work impossible. We do not consider other variants of atypical work such as self-employment or multiple job holding. The earnings variable refers to respondents' earnings at their main job (Statistics Canada, 2014), we therefore do not make any explicit distinction of multiple job holding in this analysis. However, we do include a dummy variable in our OLS models that captures whether the respondent had more than one job.

The methodological approach begins by estimating pooled OLS earnings equations regressing the natural logarithm of real hourly earnings on the set of characteristics described below, first for Canadian-born workers. We then estimate a pooled multinomial logistic regression model predicting the likelihood of being employed in standard versus and non-standard job. The outcome variable has four categories where the reference category is a full-time permanent job (i.e. standard employment). The model is estimated for all respondents separately by sex. In these models we denote two categories of immigrants, those born in a Western country (i.e. US, UK, Australia or Europe) or a non-Western country, also controlling for years-since-migration.³ We then re-estimate the pooled OLS models, now using the entire sample of workers (i.e. including immigrants) and interact non-standard work with two indicators of immigration: immigrants from a Western country and immigrants from a non-Western country.

As an additional way to examine the extent to which non-standard works helps (harms) immigrant workers, we estimate and decompose mean earnings gaps for each category of worker according to the well-known Blinder (1973) – Oaxaca (1973) technique. Wage gaps are comprised of two components: an explained portion that is due to differences in observable characteristics between the groups (i.e. standard versus non-standard workers, or immigrant versus Canadian-born) and an unexplained portion that is due to differential returns to those same endowments. Decompositions are estimated using STATA's Oaxaca command with the pooled option (Jann, 2008). For all sets of regressors with more than two categories, we have normalized the dummy variables to avoid concerns over the extent to which the choice of omitted reference category may influence the decomposition of earnings gaps into explained and unexplained components (Jann, 2008). Decompositions are repeated first for recent immigrants and then again for long-term immigrants. The variables included in the models and used to compute the decompositions are listed on the proceeding pages.

Human capital characteristics

- Age and age-squared
- Years-since-migration (coded '0' for Canadian-born)
- Education (7 categories, grade 8 or less is the omitted reference)
- Respondent is currently in school (coded '1' for in school, '0' otherwise)

Personal characteristics

- Marital status (3 categories, single-never married is the omitted reference)
- Presence of own children 0 to 12 years (coded '1' if at least 1 own child 0-12 years in the home, '0' if no children and/or children over the age of 12 years)
- Region of birth (3 categories, Canadian born is the omitted reference)

Employment-related variables

- Respondent holds more than one job (coded '1' for multiple job holder, '0' otherwise)
- Collective agreement coverage (coded '1' if respondent is covered by a collective agreement, '0' otherwise)
- Public sector employment (2 categories, private sector is the omitted reference)
- Industry broad classification based on 2012 NAICS (6 categories, retail trade is the omitted reference)
- Tenure at current job (4 categories, 0-5 months is the omitted reference)
- Employer size (4 categories, less than 20 employees is the omitted reference)

Geography and time

- Region (5 categories, Ontario is the omitted reference)
- Urban area ('1' if the respondent lives in an area with a population of at least 10,000 persons, '0' otherwise)
- Year of data collection (11 categories, 2016 is the omitted reference).

All descriptive statistics, models and decompositions are estimated using STATA's probability weight option with the final sampling weight provided in the LFS. The final weight is rescaled to reflect the use of 11 months of data (i.e. January for eleven years).

RESULTS

Table 1 provides full descriptive statistics for the immigrant and non-immigrant samples considered in the study. Noteworthy is the higher rates of postsecondary education among immigrant males and females relative to the Canadian-born working population, particularly for recent immigrants, which reflects the shifts in immigration policies, which preference highly skilled newcomers. For both males and females, a smaller share of recent immigrants is employed in full-time permanent work as well as voluntary part-time work as compared to Canadian-born. Relative to Canadian-born workers, recent immigrants are overrepresented in full-time, non-permanent and involuntary part-time arrangements. Long-term immigrants, on the other hand, have higher rates of full-time, permanent work and lower rates of voluntary part-time work relative to Canadian-born employees.

Earnings gaps among non-immigrants in standard and non-standard jobs

Before considering the differential impact of non-standard work on immigrants relative to non-immigrants, we first estimate the earnings discount associated with the three categories of non-standard work relative to the full-time, permanent standard for Canadian-born workers only. Table 2 shows the results of the OLS earnings

TABLE 1 Select descriptive statistics, 2006–2016 inclusive

equations estimated for Canadian-born workers. It is evident that *all* categories of non-standard work are associated with large earnings disadvantages. Considered together, conditioning on observable characteristics, males and females in non-standard employment earn approximately 13 and 12 per cent less respectively than those employed in a standard job.⁴ Considering the types of non-standard work separately, the largest disadvantages are experienced by those in involuntary part-time employment, with earnings roughly 20 and 15 per cent lower for males and females respectively as compared to those with a standard job.

Immigrant representation in standard and non-standard work

Since the LFS does not ask about racial origin, we create a proxy by dividing immigrants into two groups by source country: those born in a Western country (assumed to be 'white' and of European heritage) and those born in a non-Western country, assumed to be a person of 'colour' or a 'visible minority' in Canadian terminology, recognizing the imprecision of these assumptions. To capture the time spent in the Canadian labour market, we also include a continuous variable capturing years-since-migration (YSM).

The results of the multinomial logistic regression models estimating the probability of employment in various forms of standard and non-standard work are shown in Table 3. Overall, results reinforce previous findings that immigrants, relative to Canadian-born workers, are more likely to hold a non-standard job. Although there are two minor deviations from this pattern in the case of voluntary part-time work. First, immigrants, both male and female from a Western country are equally likely to be employed in voluntary part-time work. Second, immigrant females from a non-Western country are significantly less likely than Canadian-born women to hold a voluntary

Note: Standard errors are in parentheses. Models in columns 1 and 2 are estimated for males only, whereas Models in columns 3 and 4 are estimated for females only. Models in columns 1 and 3 include an indicator of non-standard work that encompasses all three categories of non-standard employment. Models in categories 2 and 4 show the three non-standard categories separately. Models also include the full set of control variables described in section 2 of the paper. Robust standard errors are reported in parentheses Models are weighted using p-weights with the LFS *finalwt* variable rescaled. Sample sizes are the sum of the rounded sub-group samples from Table 1 and as such could be considered as approximations.

*p < 0.05; **p < 0.01.

Note: The dependent variable is the probability of being in one of: full-time, non-permanent; part-time, voluntary; or part-time, involuntary, relative to full-time, permanent work (base category). Models include both cohorts of immigrants as well as Canadian-born respondents. Models also include the full set of control variables described in section 2 of the paper. Robust standard errors are reported in parentheses. Models are weighted using p-weights with the LFS *finalwt* variable, rescaled. Sample sizes are the sum of the rounded sub-group samples from Table 1 and as such could be considered as approximations.

* $p < 0.05$; ** $p < 0.01$.

part-time job. It should be noted that these two exceptions are not large enough to offset the overall finding that immigrants, as a whole, are more likely to be employed in non-standard jobs. It should also be noted that coefficients for immigrants from a non-Western country are larger than those for immigrants from a Western country, suggesting that even though all immigrants are more likely to be employed in non-standard work, it is even more so for immigrants from non-Western source countries. The descriptive statistics in Table 1 show that the overwhelming share of recent immigrants and the majority of long-term immigrants are from non-Western source countries. Finally, YSM is negative and statistically significant across all employment categories, suggesting that with time in Canada, immigrants become more likely to be employed in a standard (i.e. full-time, permanent) job.

Immigrant earnings in standard and non-standard work

To examine our central question, namely, whether immigrants are helped or hurt by non-standard employment, first, we estimate a pooled model controlling for immigrant-related variables, then adding non-standard categories of work and finally interacting these two dimensions (i.e. immigrant and non-standard work) (see Table 4). All immigrants across all forms of employment, standard and non-standard, experience a sizeable and statistically significant earnings penalty relative to Canadian-born workers, but the disparity is larger for those from non-Western countries. Immigrant males from Western countries, for example, earn roughly 18 per cent less than Canadian-born workers, whereas immigrant males from non-Western countries earn about 26 per cent less than their Canadian-born counterparts after controlling for observable characteristics (Table 4, column 1a). Years-since-migration (YSM) is positive and statistically significant, however, the magnitude of the coefficients are relatively small, suggesting that immigrants experience earnings growth of about 0.5 per cent for every year in Canada. Adding categories of work to the model (Table 4 columns 2a and 2b), we observe that, relative to full-time

Note: The dependent variable is the natural logarithm of hourly earnings adjusted for inflation. Models 2 and 4 add the set of non-standard work categories to the variables included in models 1 and 3. Models also include the full set of control variables described in section 2 of the paper. Robust standard errors are reported in parentheses. Models are weighted using p-weights with the LFS *finalwt* variable, rescaled. Sample sizes are the sum of the rounded sub-group samples from Table 1 and as such could be considered as approximations.

* $p < 0.05$; ** $p < 0.01$.

permanent work, all forms of non-standard employment are associated with significant earnings disadvantage and the penalties are similar to those found in Table 2 when we considered only Canadian-born workers.

Finally, Table 4 columns 3a and 3b include interactions of non-standard work with the two immigrant variables, born in a Western country and born in a non-Western country. To minimize the number of interactions, we chose a more parsimonious specification whereby all forms of non-standard work are combined into one variable, 'all non-standard work.' Looking at the interaction terms, the only significant interaction is between non-standard work and immigrants from a

non-Western country; which is, interestingly, *positive*. It suggests that earnings disadvantage of non-Western immigrants in non-standard jobs was slightly less (roughly 5.3% for males and 4.1% for females) than the earnings disadvantage of non-Western immigrants in standard jobs. Although a full exploration of this counter-intuitive effect is outside the scope of this paper, we do, however, discuss some possible explanations for this effect in the next section.

It is important to point out that this finding should not be interpreted independent of the main effects of being an immigrant from a non-Western country as well as being in non-standard employment, which are both large and negative. Although immigrants from non-Western countries fare somewhat better in non-standard work relative to their counterparts in standard jobs, this effect is not large enough to overcome the overall earnings gap experienced by immigrants across all types of employment. Immigrants as a group remain materially worse off in terms of earnings on account of the deep discounts associated with their country of origin and location in non-standard employment.

A deeper understanding of earnings disparities between immigrants and non-immigrants in various forms of employment can be obtained by decomposing the total 'raw' earnings gap into an 'explained' component that is attributable to explanatory variables included in our models and 'unexplained' component, as described earlier. These results can be found in the Appendix 1 – see Table A1. Due to space limitations, we present only a summary of the decompositions.⁵ Among recent immigrant males, the largest disparities are observed for those employed in full-time, permanent work: they earn roughly 0.190 log points (approx. 17 per cent) less than Canadian-born males. This 'raw' gap of 0.190 log points is made up of 0.204 log points that is not explained by the variables included in our model and a –0.014 log points that can be attributed to the human capital variables included in our model, that is the explained component. Noteworthy is the negative sign on the coefficient of the explained portion of the earnings gap, suggesting that if the immigrants had the same distribution of endowment characteristics as Canadian-born workers, the earnings disparities between the two groups would be even *larger*. This finding is suggestive of the large literature documenting the fact that immigrants in Canada are more educated than native-born workers and foreign education and experience are frequently discounted (see Reitz, 2011). Recent immigrant males in full-time, non-permanent work earn 0.133 log points (approx. 12 per cent) less than similarly employed Canadian-born males, roughly (negative) 81.2 per cent of which is explained by the variables included in the models, leaving 181 per cent owing to differential returns to those observable characteristics. A relatively small, but statistically significant earnings disparity exists between recent immigrant and Canadian-born males employed in voluntary part-time work, at roughly 3 per cent. The earnings gap between recent immigrant and Canadian-born males in involuntary part-time work is not statistically significant. Long-term immigrant males employed in full-time, permanent work experience a small disparity (0.023 log points) relative to similarly employed Canadian-born males. In both categories of part-time work, long-term immigrant males earn *more* than similarly employed Canadian-born males. A similar pattern of earnings disparities is also observed among females. However, this raw wage premium reflects only the difference in mean wages between the two groups and must be interpreted in light of the negative coefficient on the explained portion of the earnings gap, once again, pointing to the discounting of immigrant human capital characteristics.

SUMMARY OF RESULTS AND DISCUSSION

We set out to investigate if non-standard forms of employment affect the immigrant earnings gap. We knew from previous research that immigrants (and especially, new immigrants) face a large and significant earnings disadvantage relative to their Canadian-born counterparts but what was less known was whether the immigrant disadvantage in standard jobs carries over to non-standard jobs as well.

First, we find that while recent immigrants are less likely to be in standard employment relative to Canadian-born workers, years-since-migration is negatively associated with the probability of non-standard employment suggesting that over time, immigrants do become more likely to access standard jobs. Immigrants born in non-Western countries, however, are even more likely to be employed in non-standard work than immigrants

from Western nations. Second, labour market outcomes for immigrants appear to improve over time. This finding is robust across two different methods used in our analyses to capture the temporal effect: contrasting recent immigrants with longer-term immigrants in the decomposition of earnings gaps across employment categories and by including the years-since-migration (YSM) variable which is negatively correlated with the likelihood of being in a non-standard job and positively related to earnings.

We also find that earnings are substantially lower in all three forms of non-standard employment (full-time, non-permanent; voluntary part-time; and involuntary part-time) relative to the full-time, permanent 'standard' job. These findings corroborate earlier findings that non-standard jobs are generally less desirable compared to standard jobs. Overall, we find immigrant-non-immigrant earnings gaps to be the largest among standard workers and relatively smaller in part-time and full-time non-permanent work. It is worth noting that we found that long-term immigrants who have been in the labour market for ten or more years, actually enjoyed mean earnings slightly *higher* than their native-born counterparts in part-time jobs.

This finding is both counter-intuitive and revealing of some labour market processes that have not been apparent in previous research on immigrant earnings. At one level, that long-term immigrants appear to enjoy a slight earnings advantage can be seen as a success story in the immigrant narrative. However, any enthusiasm for this finding needs to be tempered by two considerations. First, the small mean earnings advantage of long-term immigrants in part-time work is not sufficiently large in magnitude to overcome the much larger earnings penalty associated with part-time employment in general. Second, the mean earnings premium in part-time work experienced by long-term immigrants may be suggestive of a low-wage trap for immigrants. It is possible that immigrants upon arrival are so disadvantaged that they end up taking a non-standard job because these are the only jobs easily available to them. Once they take the non-standard job, they tend to keep it because they are economically dependent on these earnings and become discouraged from seeking standard employment. Over many years as their earnings rise these workers become even more dependent on the job and ever so less likely to leave the non-standard job lest they are unable to find a better job. In this way, non-standard jobs may act like traps for immigrants. This is also a plausible, albeit a partial, explanation for why some studies have found a persistent earnings gap between immigrants and the native-born. Large scale longitudinal data would be necessary to empirically examine this conjecture.

We also find that for long-term immigrants in full-time permanent work, the earnings disadvantage is smaller. Together with the findings for non-standard employment, the picture that emerges is that the earnings disadvantage that immigrants face upon arrival decreases over time across both standard and non-standard jobs but the rate of this narrowing in earnings also slows down over time. These findings are consistent with the prior research evidence of persistence in an earnings gap for immigrants that lasts for decades.

We also note important differences between immigrants from Western and non-Western countries. Specifically, non-Western born immigrants are even more likely to be employed in non-standard work and have even lower earnings than immigrants from Western countries. Interestingly, the earnings disparity between non-Western immigrants and Canadian-born workers is smaller in non-standard work than it is in standard jobs; however, this in no way compensates for the overall earnings penalty of both non-standard employment and being an immigrant from a non-Western country. We can conclude, then, that non-Western born immigrants fare worse than their counterparts from Western nations and both are comparatively disadvantaged relative to Canadian-born workers. The fact that earnings gaps are smaller in non-standard work is of little surprise or consolation.

A number of important limitations bear mention and give rise to potentially fruitful directions of future research. First, the data used in this analysis are cross-sectional; therefore, we are unable to determine the extent to which immigrant transition in and out of non-standard work and if associated earnings penalties have a subsequent scarring effect on future income. Fuller (2011), for example, found that the effect of temporary employment was not different for immigrants relative to non-immigrants. While Zhang and Banerjee (2019), found that part-time employment in the first few years of arrival had a significant negative effect on immigrants' long-term earnings trajectories. Second, the Labour Force Survey does not include a visible minority indicator or variables related

to language proficiency, which are known to be important determinants of both earnings and employment type. Therefore, the Canadian-born reference group includes visible minorities and Indigenous persons, groups that often experience earnings disadvantages (e.g. Pendakur & Pendakur, 2011; George & Kuhn, 1994), meaning that earnings gaps reported here may be smaller than if the reference category were further restricted to Canadian-born, non-visible minority, non-Indigenous workers.⁶ To attempt to capture some of the important ethnocultural factors that may influence employment outcomes, we do divide immigrants into those born in Western countries and those born in non-Western countries, however, this is a very rough proxy. Given the relatively small sample of immigrants in our study, the recent and long-term cohorts are large. Therefore, future research might consider if and when the proportions of immigrants across various forms of employment reaches parity with Canadian-born workers. Finally, while we do acknowledge it, we do not formally correct for potentially important selection effects into the various categories of work. Hence, some caution in the interpretation of these results is warranted. Future research might endeavour to disentangle the selection into non-standard work and whether such mechanisms are different for immigrants versus non-immigrants.

Future research that incorporates both quantitative and qualitative accounts of immigrants' experiences in non-standard work would be helpful in adding to our understanding of the role of non-standard employment in the labour market assimilation of recent immigrants in Canada. Attitudes towards employment have been shown to vary between immigrants and Canadian-born, with immigrants placing greater emphasis on employment as a means of survival as opposed to the prospect of career development (Bauder, 2006). Undoubtedly this finding reflects the challenges cited earlier that many newcomers face in securing appropriate employment in the host country. Research that examines the potentially different attitudes towards non-standard employment between recent immigrant and Canadian-born workers as well as accounts of lived experiences of immigrants' transitions into and out of non-standard employment would add to our understanding of non-standard work as a 'trap' or a 'stepping stone' (Fuller, 2011, 161) for recent immigrants.

CONCLUSIONS

In this paper we have examined the intersection of two prominent trends in the labour market, namely, the growth in non-standard jobs and the sizeable and growing presence of immigrants. We find that immigrants are more likely to be employed in full-time, temporary work and involuntary part-time work. Moreover, we find this result to be even stronger for immigrants from non-Western countries as compared to immigrants born in a Western country. In short, immigrants, particularly those from non-Western countries, are overrepresented in lower-paying non-standard jobs. As for earnings, immigrants are most disadvantaged in standard employment and the least in part-time work. In fact, long-term immigrants appear, on average, to earn slightly *more* in part-time jobs than do the non-immigrants.

Two potential narratives, not necessarily mutually exclusive, are suggested by our findings. First, it appears that non-standard jobs have provided a port of entry to many a recent immigrant. In this respect, these jobs have enabled the new immigrant to 'break-in' to the Canadian labour market. By providing opportunities to acquire Canadian experience, these jobs facilitate immigrant integration. Over time, some of these immigrants find standard jobs.

However, this benign view of non-standard jobs obscures a less rosy reality for immigrants. The second possible narrative that emerges from these findings is that immigrants take the less desirable non-standard jobs in a labour market because they face tough barriers in accessing standard jobs. It is also likely the case that the typical immigrant taking the non-standard job is over-qualified for the job and can easily master the skills needed to perform the job with proficiency. As a result, their pay improves over time and they tend to stay in these jobs for a variety of reasons. The upshot is a cumulative overrepresentation of immigrants in non-standard jobs whereby such forms of employment act more like a trap rather than an opportunity.

There are many adverse implications of being employed in non-standard work in the short- and the long-term. Some studies have linked non-standard work to increased marginalization, as measured by access to training and consultation in the workplace, across both professional and non-professional occupations (Hoque and Kirkpatrick 2003). It is also likely that immigrants in non-standard jobs would experience a depreciation in their human capital if they are under-employed for long periods in such work (Fuller, 2011, 161).

Our findings suggest that non-standard jobs and their prevalence in the economy at-large and among immigrants is an important issue for research as well as policy. The integration of immigrants into the mainstream cannot be addressed fully without addressing the problems and opportunities that non-standard jobs present. Many factors that the immigrant assimilation research literature identifies as helping immigrants are absent in non-standard jobs. For example, presence of unions and occupational licensing were found by Zhang (2019) to improve immigrant labour market outcomes such as employment and earnings. Gomez et al (2015) found that immigrants benefit proportionally more than Canadian-born workers from employment in a regulated occupation. But, for immigrants in non-standard employment, few of these conditions apply. For example, few non-standard jobs afford the immigrant a chance to join a union (Gomez and Lamb, 2019) or to obtain occupational licensing (Gomez et al, 2015). So, many of these efforts aimed at improving the lot of immigrants are irrelevant to the context of non-standard jobs. If non-standard jobs and immigrants are to continue to form a significant share of the labour market in Canada and if the policy goal is to facilitate mainstreaming of immigrants, future research and policy would have to consider ways to improve working conditions in non-standard employment. By this we mean not only earnings and benefits, but also the opportunity to develop skills that would lead to higher earnings in the future.

ACKNOWLEDGEMENTS

This research was supported by a grant from the Partnership for Change: The RBC Immigrant Diversity and Inclusion Project at Ryerson University. This research was also supported by funds to the Canadian Research Data Centre Network (CRDCN) from the Social Science and Humanities research Council (SSHRC), the Canadian Institute for Health Research (CIHR), and the Canadian Foundation for Innovation (CFI) and Statistics Canada. An earlier version of this research was presented at the International Labour and Employment Relations Association (ILERA) World Congress in July 2018, we are grateful for the comments received. This paper was also presented at the Labour and Employment Relations (LER) annual meetings in June 2019; we are grateful for comments and suggestions received from the attendees. We wish to acknowledge Emilie-Andrée Jabouin for her work as a research assistant on this project and her contribution to the manuscript. ENDNOTES

1. The LFS employs a complex sampling design that is explained in detail the Methodology of the Labour Force Survey (Statistics Canada, 2017).

2. To adjust for inflation, we use using the Canadian CPI historical, not seasonally adjusted values obtained from Statistics Canada.
3. In this specification, we include years-since-migration, a continuous variable, instead of two dummy variables for recent and long-term immigrant.
4. The coefficients on dummy variables in the OLS regressions are converted to percentages for ease of interpretation following Halvorsen and Palmquist (1980, 474) the per cent effect is calculated taking $[\exp(\text{coeff.}) - 1] \times 100$.
5. The detailed sub-decompositions and earnings equations are available from the authors upon request.
6. The LFS does include variables denoting Indigenous identity. A similar analysis of wage disparities across non-standard categories of work comparing Indigenous, non-Indigenous and immigrant workers can be found in Lamb and Verma (2019).

Approx. Sample Size	207,640	15,040	21,930	10,190	182,360	13,450	49,250	21,520

Note: Standard errors are in parentheses. Explained and unexplained portions of the earnings gaps may not sum to the raw gap due to the loss of precision when rounding each cell to three decimal places. The Oaxaca command was run using the relax option as models contain variables (years-since-migration and Born in a Western or Non-Western country) that only have values for immigrants; Canadian-born respondents were set to '0' for these variables. Among immigrants, born in a non-Western country is the omitted reference category in the immigrant models. Sample sizes are computed using the proportions in Table 1 and rounded total sample sizes for the immigrant and non-immigrant sub-groups, as such they could be considered as approximations. Sample sizes for each column are the sum of the Canadian-born and immigrant groups being compared in each employment category. Approximate sample sizes are rounded to the nearest multiple of 10.
